iSectAI Developer Paid Trial

Database Architecture & Admin Dashboard

Technology: Supabase or another database/backend platform of your choice, along with a frontend framework of your choice.

---

1. Project Overview

iSectAI provides AI-powered services to medical clinics and service businesses. We're planning a platform where multiple businesses can be managed through a centralized system.

For this paid trial, we'd like you to build a simple **internal admin dashboard prototype** demonstrating your approach to database architecture, development, and problem-solving.

The dashboard is intended for the iSectAI administrator to monitor businesses and view relevant information across the platform.

2. Project Requirements

A. Database Architecture and Design

We'd like to see how you would approach designing a database that supports multiple medical clinics and service businesses.

For your demonstration, include at least three fictional businesses:

- Two medical clinics
- One service business (plumbing, HVAC, electrical, etc.)

You may choose your own fictional business names and sample data.

We're not requiring a specific database structure, schema organization, or architecture. You're free to implement the approach you believe works best.

We're currently using Supabase, but we haven't finalized it as our long-term database solution. You may choose another platform if you believe it's a better option for iSectAI. If you do, please briefly explain why you prefer it over Supabase.

Build only enough of the database to demonstrate your approach through the admin dashboard.

B. Internal Admin Dashboard

Build a simple working dashboard for the iSectAI administrator.

It should demonstrate:

- A list of businesses using the platform.
- Basic information about each business.
- A way to view business-specific records, such as appointments or jobs.
- At least one working connection to your chosen database/backend platform.

The interface doesn't need to be polished. Feel free to use your creativity when designing the layout, navigation, and functionality.

Focus on a working demonstration rather than building a complete application.

C. Architecture and Security

Briefly explain:

- Why you chose your database architecture and technology.
- How your design supports multiple businesses and industries.
- How you would keep each business's information separate and secure.
- How you would distinguish internal administrator access from customer access in a production version.
- What advantages or limitations your approach has.
- What you would improve or add in a production version.

3. Expected Deliverables

Please submit:

1. **Working Admin Dashboard:** A simple functional prototype connected to your database.
2. **Database Structure:** Schema or database configuration with fictional sample data.
3. **Source Code:** A GitHub repository or project folder containing your implementation.
4. **Setup Instructions:** Clear instructions for running the project, setting up the database, and loading the sample data.
5. **Architecture Explanation:** A brief explanation of your design decisions, technology choices, and possible improvements.

Submission: A short screen recording demonstrating your work is welcome but optional. A GitHub repository containing the project and everything needed to reproduce the demonstration is sufficient.

4. Development Approach

You're free to use your preferred development tools, frameworks, and AI assistants.

Please work in your own development environment using fictional data. Access to our existing production system is not part of this trial.

Focus on demonstrating your technical approach, implementation, and design decisions rather than building a production-ready application.

5. Evaluation Criteria

We'll primarily evaluate:

- **Technical approach:** How you plan and structure your solution.
- **Database architecture:** How you organize records, relationships, and multiple businesses.
- **Working implementation:** Whether your database and admin dashboard function together.
- **Problem-solving:** How you make decisions and address technical challenges.
- **Creativity:** Your approach to dashboard functionality and user experience.
- **Maintainability:** How understandable and organized your implementation is.

We don't expect a finished product. We'd rather see a simple, well-thought-out prototype than an ambitious but incomplete application.

Most importantly, we're interested in understanding why you made certain decisions, not just seeing the final result. Be prepared to explain your approach, its limitations, and what you would improve with more development time.
